### Tutorial On Multivariate Logistic Regression

5.1 Relationship to Linear Regression Note that the gradient in multinomial logistic regression is identical to the gradient in multivariate linear regression,  $r_i = -y_i | (46)$  The Hessians would be also very simmlar. In linear regression  $\frac{\partial}{\partial \theta_j} = x_j w_j (47)$  and in logistic regression  $\frac{\partial}{\partial \theta_j} = x_j w_j (48)$

### Tutorial on Multinomial Logistic Regression

Logistic Regression is used to assess the likelihood of a disease or health condition as a function of a risk factor (and covariates). Both simple and multiple logistic regression, assess the association between independent variable(s) (X i) — sometimes called exposure or predictor variables — and a dichotomous dependent variable (Y) — sometimes called the outcome or response variable.

Logistic Regression is used to assess the likelihood of an event that depends on pcovariates or independent variables. Then, using an inv.logit formulation for modeling the probability, we have:  $\pi(x) = e^{\theta+1X}$

Advantages and Disadvantages of Logistic Regression; Logistic Regression. Logistic regression is a statistical method for predicting binary classes. The outcome or target variable is dichotomous in nature. Dichotomous means there are only two possible classes. For example, it can be used for cancer detection problems.

In multinomial logistic regression you can also consider measures that are similar to R 2 in ordinary least-squares linear regression, which is the proportion of variance that can be explained by the model. In multinomial logistic regression, however, these are pseudo R 2 measures and there is more than one, although none are easily interpretable.

The Logistic Regression is a regression model in which the response variable (dependent variable) has categorical values such as True/False or 0/1. It actually measures the probability of a binary response as the value of response variable based on the mathematical equation relating it with the predictor variables.

Multiple logistic regression can be determined by a stepwise procedure using the step function. This function selects models to minimize AIC, not according to p-values as does the SAS example in the Handbook. Note, also, that in this example the step function found a different model than did the procedure in the Handbook.
